

Ranch-level Economics of Prescribed Grazing in MLRA 32 (northern Wyoming)

May 2019

Introduction

Capturing potential gains from prescribed grazing as the result of increased cattle production requires the development of sophisticated models of cattle production dynamics. To begin filling this information gap, this study seeks to quantify and compare the impact on ranch profits from two prescribed grazing conservation practices: 1) rotational grazing and 2) rotational grazing plus rest. The Natural Resources Conservation Service (NRCS) offers both technical assistance and financial incentives for ranchers interested in adopting prescribed grazing programs, so understanding how these practices affect ranchers' bottom lines is critically important.

Methods

Two representative ranch types were identified from enterprise budgets for this major land resource area (MLRA). Public ranch types use rangeland managed by the federal or state government (Bureau of Land Management, United States Forest Service, and/or State), as well as private rangeland. Private ranch types operate solely on privately owned rangelands. Representative ranches were modeled as profit-maximizing operations, with a planning horizon of 40 years. The Net Present Value (NPV) of the ranch's net cash flow was calculated using a 7% discount rate,

¹ A factor of proximity of cattle to a water source

averaged from 100 cattle sales price scenarios developed using Cattlefax price data.

Researchers then created impact models, working with a panel of NRCS advisors. Project size in acres was estimated from the number of Animal Unit Months (AUMs) given in enterprise budgets, vegetation production information detailed in Ecological Site Descriptions, and an assumed 25% Harvest Efficiency (HE) and a 70% water distance factor (WDF)¹. Following implementation of a prescribed grazing conservation practice, at least two new water developments were added to the model. Additional water developments were added if required to achieve 90% WDF. Fencing, water developments, and other costs associated with prescribed grazing were assumed to be supported through the Environmental Quality Incentives Program (EQIP) (3/4 of project costs) and by NRCS incentive payments. Since prescribed grazing also may result in harvest efficiency gains, two harvest efficiency scenarios are considered for each impact model -- no change, and 5% increase (i.e., 30% HE).

Results

Table 1 and 2 illustrate the results. Table 1 shows that both representative ranch types

Table 1. Installation costs and net project cost after EQIP and NRCS incentive payments.

Ranch Type	Project Size (Acres)	Initial Installation cost	Incentive Payments ²		Present Value of Incentives Received and Costs of Installation, Operation and Maintenance	
			Rotation	Rotation+ Rest	Rotation	Rotation+ Rest
Large Public	15,389	\$234,734	\$47,399	\$116,343	\$20,087	\$201,300
Small Private	9,789	\$184,104	\$30,148	\$74,001	-\$2,669	\$112,592

Table 2. Baseline and impact model results, showing changes in cattle production and the Net Present Value (NPV) of the ranch's net cash flow over 40 years.

Ranch Type	Base-line NPV (000's)	Impact (+/-)			Impact (+/-), with 5% HE Increase		
		Herd Size	Rotation NPV	Rotation + Rest NPV	Herd Size	Rotation NPV	Rotation + Rest NPV
Large Public	\$1,245.7	+3%	+8%	+23%	+7%	+16.5%	+31%
Small Private	\$377.3	+6%	+14%	+45%	+14%	+30%	+61%

would see a net gain (highlighted in green) by adopting prescribed grazing rotation plus rest, just from EQIP and NRCS incentive payments alone. However, only the Large Public ranch would experience a net gain if adopting the second prescribed grazing option of rotation only, without rest. Table 2 builds upon Table 1 and summarizes the impact for the two representative ranches when modeling cattle production gains as the result of prescribed grazing in addition to incentives. Profit gains are shown in green. Either harvest efficiency results in profit gains for all representative ranches in this MLRA for either prescribed grazing option.

Conclusions

- These results highlight profit gains available to ranches within this MLRA from conservation program participation.
- Our rigorous models show increased cattle production numbers (Table 2) as the result of prescribed grazing. Ranchers may be unaware of this possible added benefit of NRCS programs; education

about such benefits may promote conservation program participation.

- Project size (in acres) and assumed harvest efficiency benefits can change practice adoption outcomes for both types of prescribed grazing. Ranches with larger project sizes may see greater gains in WDF and receive larger total incentive payments.
- There are possible non-market and ecological benefits from prescribed grazing not quantified here. Further research is needed to understand how these values affect program adoption and economic outcomes.
